Data Cleaning Report

To prepare the Corporate Blueprint Cohort 1 assessment dataset for analysis, I carried out several data-cleaning activities to improve the quality, consistency, and reliability of the data.

The first step was to review the dataset for duplicate records. After checking all learner entries, no duplicate records were found, so all records were retained in the dataset.

Next, I checked for missing values across the assessment columns. Any blank cells were left unchanged because they represented learners who had not completed certain assessments. These missing values were useful in determining each learner's completion status and were not replaced with estimated values.

I also standardized the learner names by converting them to proper case to ensure consistency throughout the dataset. This makes the data easier to read and reduces errors during analysis.

After standardizing the text fields, I verified the assessment scores to ensure they were correctly recorded. I then created additional calculated columns to support further analysis. These included:

- **Student ID** – A unique identifier created for each learner.
- **Total Score** – The sum of all assessment scores for each learner.
- **Average Score** – The average score across completed assessments.
- **Completion Status** – Indicates whether a learner completed all required assessments.
- **Performance Category** – Learners were classified as **Excellent**, **Good**, **Fair**, or **Needs Improvement** based on their average scores.

Finally, I reviewed the cleaned dataset to confirm that all calculations were accurate. Overall, the cleaning process improved the organization, consistency, and usability of the dataset while preserving the integrity of the original assessment records.
